# Package 'WebPower' 

October 13, 2023
Title Basic and Advanced Statistical Power Analysis
Version 0.9.4
Date 2023-10-13
Author Zhiyong Zhang [aut, cre],
Yujiao Mai [aut],
Miao Yang [ctb],
Ziqian Xu [ctb],
Conor McNamara [ctb]
Maintainer Zhiyong Zhang [johnnyzhz@gmail.com](mailto:johnnyzhz@gmail.com)
Depends R (>= 3.2.5), MASS, grDevices, graphics, lme4, lavaan, parallel, PearsonDS

Imports dplyr, stats
License GPL (>= 3)
Description This is a collection of tools for conducting both basic and advanced statistical power analysis including correlation, proportion, t-test, one-way ANOVA, two-way ANOVA, linear regression, logistic regression, Poisson regression, mediation analysis, longitudinal data analysis, structural equation modeling and multilevel modeling. It also serves as the engine for conducting power analysis online at [https://webpower.psychstat.org](https://webpower.psychstat.org).

## Description

This is a collection of tools for conducting both basic and advanced statistical power analysis including correlation, proportion, t-test, one-way ANOVA, two-way ANOVA, linear regression, logistic regression, Poisson regression, mediation analysis, longitudinal data analysis, structural equation modeling and multilevel modeling. It also serves as the engineer for conducting power analysis online at https://webpower.psychstat.org.

## Details

This is a collection of tools for conducting both basic and advanced statistical power analysis including correlation, proportion, t-test, one-way ANOVA, two-way ANOVA, linear regression, logistic regression, Poisson regression, mediation analysis, longitudinal data analysis, structural equation modeling and multilevel modeling. It also serves as the engineer for conducting power analysis online at https://webpower.psychstat.org.

## References

Zhang, Z., \& Yuan, K.-H. (2018). Practical Statistical Power Analysis Using Webpower and R (Eds). Granger, IN: ISDSA Press.

## Description

- ID. The identification number of the subjects.
- cluster. The cluster number.
- score. The score of the subject.
- group. The group number.

## Usage

CRT2

## Format

An object of class data. frame with 8 rows and 4 columns.

## Examples

```
# ID cluster score group
# 1 1 6 0
# 2 120
# 3 2 6 1
# 4 2 5 1
# 5 3 1 0
# 6 340
# 7461
# 8441
```

## Description

- ID. The identification number of the subjects.
- cluster. The cluster number.
- score. The score of the subject.
- group. The group number.

## Usage

## CRT3

## Format

An object of class data. frame with 30 rows and 4 columns.

## Examples

```
# id cluster score group
# 1 1 1.93 0
# 2 1 1.51 0
# 3 1 2.130
# 4 1 2.96 0
# 5 1 3.840
# 6 2 3.36 1
# 7 2 3.13 1
# 8 2 1.71 1
# 9 2 3.1 1
# 10 2 2.53 1
# 11 3 2.01 2
# 12 3 4.73 2
# 13 3 3.34 2
# 14 3 0.11 2
# 15 3 3.6 2
# 16420
```

```
# 17 4 1.99 0
# 18 4 1.89 0
# 19 4 2.25 0
# 20 4 1.83 0
# 21 5 3.03 1
# 22 5 2.08 1
# 23 5 1.5 1
# 24 5 3.18 1
# 25 5 1.92 1
# 26 6 3.49 2
# 27 6 3.08 2
# 28 6 4.54 2
# 29 6 2.34 2
# 30 6 4.33 2
```

estCRT2arm Estimate multilevel effect size from data

## Description

Estimate multilevel effect size from data

## Usage

estCRT2arm(file)
estCRT3arm(file)
estMRT2arm(file)
estMRT3arm(file)

## Arguments

file a data file

## Description

- ID. The identification number of the subjects.
- cluster. The cluster number.
- score. The score of the subject.
- group. The group number.

## Usage

MRT2

## Format

An object of class data. frame with 16 rows and 4 columns.

## Examples

```
#Example data for MRT with 2 arms
# id cluster score group
# 1 1 6 0
# 2 1 2 0
# 3 1 3 1
# 4 1 3 1
# 5 2 6 0
# 6 2 100
# 7 2 7 1
# 8 2 6 1
# 9360
# 10350
# 11 3 4 1
# 12 3 4 1
# 13410
# 14480
# 15 4 10 1
# 16 4 -2 1
```

## Description

- ID. The identification number of the subjects.
- cluster. The cluster number.
- score. The score of the subject.
- group. The group number.

## Usage

MRT3

## Format

An object of class data. frame with 24 rows and 4 columns.

## Examples

```
# id cluster score group
# 1 1 2 0
# 2 1 3 0
# 3 1 2 1
# 4 1 0 1
# 5 1 3 2
# 6 1 2 2
# 7 2 1 0
# 8 240
# 9 2 2 1
# 10 2 3 1
# 112 3 2
# 12 2 1 2
# 13 3 1 0
# 14 3 4 0
# 15 3 1 1
# 16 3 1 1
# 17 3 2 2
# 18 3 0 2
# 19440
# 20430
# 21 4 1 1
# 22 4 3 1
# 23 4 3 2
# 24432
```

nuniroot

## Description

The function searches in an interval for a root (i.e., zero) of the function $f$ with respect to its first argument. The argument interval is for the input of $x$, the corresponding outcome interval will be used as the interval to be searched in.

## Usage

nuniroot(f, interval, maxlength = 100)

## Arguments

f
interval
maxlength

Function for which the root is sought.
A vector containing the end-points of the interval to be searched for the root.
The number of vaulue points in the interval to be searched. It is 100 by default.

## Value

A list with at least four components: root and f.root give the location of the root and the value of the function evaluated at that point. iter and estim.prec give the number of iterations used and an approximate estimated precision for root. (If the root occurs at one of the endpoints, the estimated precision is NA.)

## Examples

```
f <- function(x) 1+x-0.5*x^2
interval <- c(-3,6)
nuniroot(f,interval)
```

plot.lcs.power Plot the power curve for Latent Change Score Models

## Description

This function is used to plot the power analysis results for Latent Change Score Models.

```
Usage
\#\# S3 method for class 'lcs.power'
plot(x, parameter, ...)
```

## Arguments

x
parameter Parameters for features of the plot.
$\ldots \quad$ Extra arguments. It is not required.

## References

Zhang, Z., \& Liu, H. (2018). Sample Size and Measurement Occasion Planning for Latent Change Score Models through Monte Carlo Simulation. In E. Ferrer, S. M. Boker, and K. J. Grimm (Eds.) Advances in Longitudinal Models for Multivariate Psychology: A Festschrift for Jack McArdle.

$\qquad$
plot.webpower To plot Statistical Power Curve

## Description

This function is used to plot the power curves generated by webpower.

## Usage

```
\#\# S3 method for class 'webpower'
plot(x, xvar = NULL, yvar = NULL, xlab = NULL,
    ylab = NULL, ...)
```

## Arguments

| $x$ | Objects of power analysis. |
| :--- | :--- |
| xvar | The variable name used as the x (horizontal) axis. It is not required. |
| yvar | The variable name used as the y (vertical) axis. It is not required. |
| xlab | The label for the x axis. It is not required. |
| ylab | The label for the y axis. It is not required. |
| $\ldots$ | Extra arguments. It is not required. |

## Value

The plot.

## Examples

```
res <- wp.correlation(n=seq(50,100,10),r=0.3, alternative="two.sided")
plot(res)
```

print.webpower To Print Statistical Power Analysis Results

## Description

This function is used to summary the power analysis results.

## Usage

```
## S3 method for class 'webpower'
```

print(x, ...)

## Arguments

x
Object of power analysis. It is an object returned by a webpower function such as wp.anova().
$\ldots \quad$ Extra arguments. It is not required.

## Value

The printing of the input object of power analysis.

## Examples

```
res <- wp.correlation(n=50,r=0.3, alternative="two.sided")
print(res)
```

sem.effect.size Calculate the Effect Size for SEM

## Description

This function is for calculating SEM effect size.

## Usage

sem.effect.size(full.model.pop, reduced.model)

## Arguments

full.model. pop Full model (under the alternative hypothesis) with population parameters.
reduced.model Reduced model (under the null hypothesis) lavaan specification.

## Value

An object of the power analysis.
delta Effect size.
df Degrees of freedom
RMSEA RMSEA

## References

Demidenko, E. (2007). Sample size determination for logistic regression revisited. Statistics in medicine, 26(18), 3385-3397.

Zhang, Z., \& Yuan, K.-H. (2018). Practical Statistical Power Analysis Using Webpower and R (Eds). Granger, IN: ISDSA Press.

## Examples

```
    full.model.pop <-'
    y1 ~ 0.4*x
    y2 ~ 0.5*x + 0.2*y1
    y3 ~ 0.4*x
    y4 ~ 0.4*y1 + 0.4*y2 + 0.4*y3
    y1 ~~ 0.84*y1
    y2 ~~ 0.61*y2
    y3 ~~ 0.84*y3
    y4 ~~ 0.27*y4
    reduced.model <-'
    y1 ~ x
    y2 ~ x
    y3 ~ x
    y4 ~ y1 + y3
```

    sem.effect.size(full.model.pop, reduced.model)
    summary. power
    
## Description

This function is used to summary the power analysis results.

## Usage

```
\#\# S3 method for class 'power'
summary (object, ...)
```

## Arguments

object Object of power analysis. It is an object returned by a webpower function for SEM based on Monte Carlo methods with class = 'power'.
$\ldots \quad$ Extra arguments. It is not required.

## Value

The summary of the input object of power analysis.

```
wp.anova Statistical Power Analysis for One-way ANOVA
```

## Description

One-way analysis of variance (one-way ANOVA) is a technique used to compare means of two or more groups (e.g., Maxwell \& Delaney, 2003). The ANOVA tests the null hypothesis that samples in two or more groups are drawn from populations with the same mean values. The ANOVA analysis typically produces an F-statistic, the ratio of the bewteen-group variance to the withingroup variance.

## Usage

wp.anova(k = NULL, $\mathrm{n}=\mathrm{NULL}, \mathrm{f}=\mathrm{NULL}, \mathrm{alpha}=0.05$, power $=$ NULL, type = c("overall", "two.sided", "greater", "less"))

## Arguments

$k \quad$ Number of groups.
$\mathrm{n} \quad$ Sample size.
$\mathrm{f} \quad$ Effect size. We use the statistic f as the measure of effect size for one-way ANOVA as in Cohen (1988). Cohen defined the size of effect as: small 0.1, medium 0.25 , and large 0.4.
alpha Significance level chosed for the test. It equals 0.05 by default.
power Statistical power.
type Type of test ("overall" or "two.sided" or "greater" or "less"). The default is "two.sided". The option "overall" is for the overall test of anova; "two.sided" is for a contrast anova; "greater" is testing the between-group vairance greater than the within-group, while "less" is vis versus.

## Value

An object of the power analysis.

wp. anova.binary

Statistical Power Analysis for One-way ANOVA with Binary Data

## Description

The power analysis procedure for one-way ANOVA with binary data is introduced by Mai and Zhang (2017). One-way ANOVA with binary data is used for comparing means of three or more groups of binary data. Its outcome variable is supposed to follow Bernoulli distribution. And its overall test uses a likelihood ratio test statistics.

## Usage

wp. anova.binary (k = NULL, $\mathrm{n}=\mathrm{NULL}, \mathrm{V}=\mathrm{NULL}$, alpha $=0.05$, power = NULL)

## Arguments

k
Number of groups.
n Sample size.
V Effect size. See the research by Mai and Zhang (2017) for details.
alpha Significance level chosed for the test. It equals 0.05 by default.
power Statistical power.

## Value

An object of the power analysis.

## References

wp. anova. count Statistical Power Analysis for One-way ANOVA with Count Data

## Description

The power analysis procedure for one-way ANOVA with count data is introduced by Mai and Zhang (2017). One-way ANOVA with count data is used for comparing means of three or more groups of binary data. Its outcome variable is supposed to follow Poisson distribution. And its overall test uses a likelihood ratio test statistics.

## Usage

```
wp.anova.count(k = NULL, \(\mathrm{n}=\mathrm{NULL}, \mathrm{V}=\mathrm{NULL}, \mathrm{alpha}=0.05\),
    power = NULL)
```

## Arguments

$k \quad$ Number of groups.
$\mathrm{n} \quad$ Sample size.
V Effect size. See the research by Mai and Zhang (2017) for details.
alpha Significance level chosed for the test. It equals 0.05 by default.
power Statistical power.

## Value

An object of the power analysis.

## Description

A longitudinal design often involves data collection on multiple variables from multiple participants at multiple times. Growth curve models (GCM) are structural equation models for longitudinal data analysis (McArdle \& Epstein, 1987; McArdle \& Nesselroade, 2014). Latent change score models (LCSM) combine difference equations with growth curves to investigate change in longitudinal studies . LCSM provied an efficient way to model nonlinear trajectory (e.g., McArdle, 2000; McArdle \& Hamagami, 2001; Hamagami et al., 2010). This function is used to conduct power analysis for bivariate LCSMs based on a Monte Carlo method ( a method also used by Muthén \& Muthén, 2002; Thoemmes et al., 2010; Zhang \& Wang, 2009; Zhang, 2014). For each Monte Carlo replication, the Maximum likelihood ratio test is used for the model, while the Wald test is used for the parameter test. The method can obtain the power for testing each individual parameter of the models such as the change rate and coupling parameters.

## Usage

$$
\begin{aligned}
& \text { wp. } \operatorname{blcsm}(\mathrm{N}=100, \mathrm{~T}=5, \mathrm{R}=1000 \text {, betay }=0 \text {, my } 0=0 \text {, mys }=0 \text {, } \\
& \text { varey }=1 \text {, vary0 }=1 \text {, varys }=1 \text {, vary0ys }=0 \text {, alpha }=0.05 \text {, } \\
& \text { betax }=0, m x 0=0, m x s=0, \text { varex }=1 \text {, varx } 0=1 \text {, varxs = } 1 \text {, } \\
& \text { varx0xs }=0, \operatorname{var} x 0 y 0=0, \operatorname{varx0ys}=0, \operatorname{vary0xs}=0, \operatorname{varxsys}=0 \text {, } \\
& \text { gammax }=0 \text {, gammay }=0, \ldots \text { ) }
\end{aligned}
$$

## Arguments

N
T
R Number of replications for the Monte Carlo simulation. It is 1000 by default.
betay Parameter in the model: The compound rate of change for variable y . Its default value is 0 .
my0 Parameter in the model: Mean of the initial latent score for variable y . Its default value is 0 .
mys Parameter in the model: Mean of the linear constant effect for variable y. Its default value is 0 .
varey Parameter in the model: Variance of the measurement error/uniqueness score for variable $y$. Its default value is 1 .
vary0 Parameter in the model: Variance of the initial latent score for variable y. Its default value is 1 .
varys Parameter in the model: Variance of the linear constant effect for variable y. Its default value is 0 .
vary0ys Parameter in the model: Covariance of the initial latent score and the linear constant effect for variable $y$. Its default value is 0 .

| alpha |  |
| :--- | :--- |
| betax | significance level chosed for the test. It equals 0.05 by default. |
| Parameter in the model: The compound rate of change for variable x. Its default |  |
| value is 0. |  |
| Parameter in the model: Mean of the initial latent score for variable $x$. Its default |  |
| value is 0. |  |
| Parameter in the model: Mean of the linear constant effect for variable x. Its |  |
| default value is 0. |  |
| Parameter in the model: Variance of the measurement error/uniqueness score |  |
| for variable x. Its default value is 1. |  |

## Value

An object of the power analysis. The output of the R function includes 4 main pieces of information for each parameter in the model. The first is the Monte Carlo estimate (mc.est). It is calculated as the mean of the R sets of parameter estimates from the simulated data. Note that the Monte Carlo estimates should be close to the population parameter values used in the model. The second is the Monte Carlo standard deviation (mc.sd), which is calculated as the standard deviation of the R sets of parameter estimates. The third is the Monte Carlo standard error (mc.se), which is obtained as the average of the R sets of standard error estimates of the parameter estimates. Lastly, mc.power is the statistical power for each parameter.

wp.correlation Statistical Power Analysis for Correlation

## Description

This function is for power analysis for correlation. Correlation measures whether and how a pair of variables are related. The Pearson Product Moment correlation coefficient (r) is adopted here. The power calculation for correlation is conducted based on Fisher's z transformation of Pearson correlation coefficent (Fisher, 1915, 1921).

## Usage

wp.correlation( $\mathrm{n}=\mathrm{NULL}, \mathrm{r}=$ NULL, power $=$ NULL, $\mathrm{p}=0$, $\mathrm{rho0}=0$, alpha $=0.05$, alternative $=c(" t w o . s i d e d ", ~ " l e s s ", ~ " g r e a t e r "))$

## Arguments

n
Sample size.
$r \quad$ Effect size or correlation. According to Cohen (1988), a correlation coefficient of $0.10,0.30$, and 0.50 are considered as an effect size of "small", "medium", and "large", respectively.
power Statistical power.
p Number of variables to partial out.
rho0 Null correlation coefficient.
alpha $\quad$ Significance level chosed for the test. It equals 0.05 by default.
alternative Direction of the alternative hypothesis ("two.sided" or "less" or "greater"). The default is "two.sided".

## Value

An object of the power analysis.

wp.crt2arm

## Description

Cluster randomized trials (CRT) are a type of multilevel design for the situation when the entire cluster is randomly assigned to either a treatment arm or a contral arm (Liu, 2013). The data from CRT can be analyzed in a two-level hierachical linear model, where the indicator variable for treatment assignment is included in second level. If a study contains multiple treatments, then mutiple indicators will be used. This function is for designs with 2 arms (i.e., a treatment and a control). Details leading to power calculation can be found in Raudenbush (1997) and Liu (2013).

## Usage

```
wp.crt2arm(n = NULL, f = NULL, J = NULL, icc = NULL, power = NULL,
    alpha = 0.05, alternative = c("two.sided", "one.sided"), interval = NULL)
```

## Arguments

n
f

J Number of clusters / sides. It tells how many clusters are considered in the study design. At least two clusters are required.
icc Intra-class correlation. ICC is calculated as the ratio of between-cluster variance to the total variance. It quantifies the degree to which two randomly drawn observations within a cluster are correlated.
power Statistical power.
alpha significance level chosed for the test. It equals 0.05 by default.
alternative Type of the alternative hypothesis ("two.sided" or "one.sided"). The default is "two.sided". The option "one.sided" can be either "less" or "greater".
interval A vector containing the end-points of the interval to be searched for the root.

## Value

An object of the power analysis.

## References

wp.crt3arm Statistical Power Analysis for Cluster Randomized Trials with 3 Arms

## Description

Cluster randomized trials (CRT) are a type of multilevel design for the situation when the entire cluster is randomly assigned to either a treatment arm or a control arm (Liu, 2013). The data from CRT can be analyzed in a two-level hierarchical linear model, where the indicator variable for treatment assignment is included in second level. If a study contains multiple treatments, then multiple indicators will be used. This function is for designs with 3 arms (i.e., two treatments and a control). Details leading to power calculation can be found in Raudenbush (1997) and Liu (2013).

## Usage

wp.crt3arm( $\mathrm{n}=\mathrm{NULL}, \mathrm{f}=\mathrm{NULL}, \mathrm{J}=\mathrm{NULL}, \mathrm{icc}=$ NULL, power $=$ NULL, alpha $=0.05$, alternative $=c(" t w o . s i d e d ", ~ " o n e . s i d e d ")$,
type = c("main", "treatment", "omnibus"), interval = NULL)

## Arguments

n
Sample size. It is the number of individuals within each cluster.
$f \quad$ Effect size. It specifies one of the three types of effects: the main effect of treatment, the mean difference between the treatment clusters, and the control clusters.
J Number of clusters / sides. It tells how many clusters are considered in the study design. At least two clusters are required.
icc Intra-class correlation. ICC is calculated as the ratio of between-cluster variance to the total variance. It quantifies the degree to which two randomly drawn observations within a cluster are correlated.
power Statistical power.
alpha significance level chosed for the test. It equals 0.05 by default.
alternative Type of the alternative hypothesis ("two.sided" or "one.sided"). The default is "two.sided". The option "one.sided" can be either "less" or "greater".
type Type of effect ("main" or "treatment" or "omnibus") with "main" as default. The type "main" tests the difference between the average treatment arms and the control arm; Type "treatment" tests the difference between the two treatment arms; and Type "omnibus" tests whether the tree arms are all equivalent.
interval A vector containing the end-points of the interval to be searched for the root.

## Value

An object of the power analysis.

wp.effect.CRT2arm Effect size calculatator based on raw data for Cluster Randomized
Trials with 2 Arms

## Description

This function is for effect size and ICC calculation for CRT with 2 arms based on empirical data. Cluster randomized trials (CRT) are a type of multilevel design for the situation when the entire cluster is randomly assigned to either a treatment arm or a contral arm (Liu, 2013). The data from CRT can be analyzed in a two-level hierachical linear model, where the indicator variable for treatment assignment is included in second level. If a study contains multiple treatments, then mutiple indicators will be used. This function is for designs with 3 arms (i.e., two treatments and a control). Details leading to power calculation can be found in Raudenbush (1997) and Liu (2013). The Effect size f specifies the main effect of treatment, the mean difference between the treatment clusters and the control clusters. This function is used to calculate the effect size with a input data set.

## Usage

wp.effect.CRT2arm(file)

## Arguments

file The input data set. The first column of the data is the ID variable, the second column represents cluster, the third column is the outcome variable, and the fourth column is the condition variable ( 0 for control, 1 for condition).

## Value

A list including effect size f and ICC.

## References

Liu, X. S. (2013). Statistical power analysis for the social and behavioral sciences: basic and advanced techniques. Routledge.

Raudenbush, S. W. (1997). Statistical analysis and optimal design for cluster randomized trials. Psychological Methods, 2(2), 173.

## Examples

```
#Empirical data set CRT2:

wp.effect.MRT2arm Effect size calculatator based on raw data for Multisite Randomized Trials with 2 Arms

## Description

This function is for effect size calculation for Multisite randomized trials (MRT) with 2 arms based on empirical data. MRTs are a type of multilevel design for the situation when the entire cluster is randomly assigned to either a treatment arm or a contral arm (Liu, 2013). The data from MRT can be analyzed in a two-level hierachical linear model, where the indicator variable for treatment assignment is included in first level. If a study contains multiple treatments, then mutiple indicators will be used. Three types of tests are considered in the function: (1) The "main" type tests treatment main effect; (2) The "site" type tests the variance of cluster/site means; and (3) The "variance" type tests variance of treatment effects. Details leading to power calculation can be found in Raudenbush (1997) and Liu (2013). This function is used to calculate the effect size with a input data set.

## Usage

wp.effect.MRT2arm(file)

## Arguments

file The input data set. The first column of the data is the ID variable, the second column represents cluster, the third column is the outcome variable, and the fourth column is the condition variable ( 0 for control, 1 for condition).

## Value

A list including effect size f .

```

| wp.lcsm | Statistical Power Curve for Univariate Latent Change Score Models <br> based on Monte Carlo Simulation |
| :--- | :--- |

## Description

A longitudinal design often involves data collection on multiple variables from multiple participants at multiple times. Growth curve models (GCM) are structural equation models for longitudinal data analysis (McArdle \& Epstein, 1987; McArdle \& Nesselroade, 2014). Latent change score models (LCSM) combine difference equations with growth curves to investigate change in longitudinal studies . LCSM provied an efficient way to model nonlinear trajectory (e.g., McArdle, 2000; McArdle \& Hamagami, 2001; Hamagami et al., 2010). This function is used to conduct power analysis for univariate LCSMs based on a Monte Carlo method ( a method also used by Muthén \& Muthén, 2002; Thoemmes et al., 2010; Zhang \& Wang, 2009; Zhang, 2014). For each Monte Carlo replication, the Maximum likelihood ratio test is used for the model, while the Wald test is used for the parameter test. The method can obtain the power for testing each individual parameter of the models such as the change rate and coupling parameters.

## Usage

wp. $\operatorname{lcsm}(\mathrm{N}=100, \mathrm{~T}=5, \mathrm{R}=1000$, betay $=0$, my $0=0$, mys $=0$, varey = 1, vary0 = 1, varys = 1, vary0ys = 0, alpha = 0.05, ...)

## Arguments

| N | Sample size. It is 100 by default. |
| :--- | :--- |
| T | Number of measurement occasions. It is 5 by default. |
| R | Number of replications for the Monte Carlo simulation. It is 1000 by default. |
| betay | Parameter in the model: The compound rate of change. Its default value is 0. |
| my 0 | Parameter in the model: Mean of the initial latent score. Its default value is 0. |
| mys | Parameter in the model: Mean of the linear constant effect. Its default value is |
| 0. |  |$\quad$| Parameter in the model: Variance of the measurement error/uniqueness score. |
| :--- |
| Its default value is 1. |

## Value

An object of the power analysis. The output of the R function includes 4 main pieces of information for each parameter in the model. The first is the Monte Carlo estimate (mc.est). It is calculated as the mean of the R sets of parameter estimates from the simulated data. Note that the Monte Carlo estimates should be close to the population parameter values used in the model. The second is the Monte Carlo standard deviation (mc.sd), which is calculated as the standard deviation of the R sets of parameter estimates. The third is the Monte Carlo standard error (mc.se), which is obtained as the average of the R sets of standard error estimates of the parameter estimates. Lastly, mc.power is the statistical power for each parameter.

## End(Not run)
```

```
wp.logistic Statistical Power Analysis for Logistic Regression
```

## Description

This function is for Logistic regression models. Logistic regression is a type of generalized linear models where the outcome variable follows Bernoulli distribution. Here, Maximum likelihood methods is used to estimate the model parameters. The estimated regression coefficent is assumed to follow a normal distribution. A Wald test is use to test the mean difference between the estimated parameter and the null parameter (tipically the null hypothesis assumes it equals 0 ). The procedure introduced by Demidenko (2007) is adopted here for computing the statistical power.

## Usage

wp. $\operatorname{logistic(n=NULL,~p0~}=$ NULL, $\mathrm{p} 1=$ NULL, alpha $=0.05$, power $=$ NULL, alternative = c("two.sided", "less", "greater"), family = c("Bernoulli", "exponential", "lognormal", "normal", "Poisson", "uniform"), parameter = NULL)

## Arguments

n
p0 $\quad \operatorname{Prob}(Y=1 \mid X=0)$ : the probobility of observieng 1 for the outcome variable Y when the predictor X equals 0 .
p1 $\operatorname{Prob}(Y=1 \mid X=1)$ : the probobility of observieng 1 for the outcome variable Y when the predictor X equals 1.
alpha significance level chosed for the test. It equals 0.05 by default.
power Statistical power.
alternative Direction of the alternative hypothesis ("two.sided" or "less" or "greater"). The default is "two.sided".
family Distribution of the predictor ("Bernoulli","exponential", "lognormal", "normal", "Poisson", "uniform"). The default is "Bernoulli".
parameter Corresponding parameter for the predictor's distribution. The default is 0.5 for "Bernoulli", 1 for "exponential", $(0,1)$ for "lognormal" or "normal", 1 for "Poisson", and $(0,1)$ for "uniform".

## Value

An object of the power analysis.

y3 ~ x
y4 ~ y1 + y3
```

wp.mc.chisq.diff(full.model.pop, full.model, reduced.model)
wp.mc.sem.basic Statistical Power Analysis for Structural Equation Modeling / Mediation based on Monte Carlo Simulation

## Description

Structural equation modeling (SEM) is a multivariate technique used to analyze relationships among observed and latent variables. It can be viewed as a combination of factor analysis and multivariate regression analysis. A mediation model can be viewed as a SEM model. Funtions wp.sem.chisq and wp.sem.rmsea provide anlytical solutions of power analysis for SEM. Function wp.mediation provides anlytical solutions of power analysis for a simple mediatoin model. This function provides a solution based on Monte Carlo simulation (see Zhang, 2014). If the model is a mediation, Sobel test is used for the mediation / indirect effects. The solution is extended from the general framework for power analysis for complex mediation models using Monte Carlo simulation in Mplus (Muthén \& Muthén, 2011) proposed by Thoemmes et al. (2010). We extended the framework in two ways. First, the method allows the specification of nonnormal data in the Monte Carlo simulation and can
thereby reflect more closely practical data collection. Second, the function wp.mc.sem.basic of a free, open-source R package, WebPower, is developed to ease power anlysis for mediation models using the proposed method.

## Usage

```
wp.mc.sem.basic(model, indirect = NULL, nobs = 100, nrep = 1000,
    alpha = 0.95, skewness = NULL, kurtosis = NULL, ovnames = NULL,
    se = "default", estimator = "default", parallel = "no",
    ncore = Sys.getenv("NUMBER_OF_PROCESSORS"), cl = NULL, ...)
```

## Arguments

\(\left.\left.$$
\begin{array}{ll}\text { model } & \begin{array}{l}\text { Model specified using lavaan syntax. More about model specification can be } \\
\text { found in Rosseel (2012). } \\
\text { indirect }\end{array} \\
\text { Indirect effect difined using lavaan syntax. } \\
\text { nobs } & \text { Sample size. } \\
\text { nrep } & \text { Number of replications for the Monte Carlo simulation. } \\
\text { alpha } & \text { significance level chosed for the test. It equals 0.05 by default. } \\
\text { skewness } & \text { A sequence of skewnesses of the observed variables. } \\
\text { kurtosis } & \begin{array}{l}\text { A sequence of kurtosises of the observed variables. } \\
\text { ovnames }\end{array} \\
\text { sames of the observed variables in the model. }\end{array}
$$\right\} \begin{array}{l}The method for calculatating the standard errors. Its default method "default" <br>

## Description

Structural equation modeling (SEM) is a multivariate technique used to analyze relationships among observed and latent variables. It can be viewed as a combination of factor analysis and multivariate regression analysis. A mediation model can be viewed as a SEM model. Funtions wp.sem.chisq and wp.sem.rmsea provide anlytical solutions of power analysis for SEM. Function wp.mediation provides anlytical solutions of power analysis for a simple mediatoin model. This function provides a solution based on Monte Carlo simulation (see Zhang, 2014) and a bootstrap method for testing the indirect /mediation effects. The solution is extended from the general framework for power analysis for complex mediation models using Monte Carlo simulation in Mplus (Muthén \& Muthén, 2011) proposed by Thoemmes et al. (2010). We extended the framework in three ways. First, we proposes a general method to conduct power analysis for mediation models based on the bootstrap method. The method is still based on Monte Carlo simulation but uses the bootstrap method to test mediation effects. Second, the method allows the specification of nonnormal data in the Monte Carlo simulation and can thereby reflect more closely practical data collection. Third, the function wp.mc.sem.boot of a free, open-source R package, WebPower, is developed to ease power anlysis for mediation models using the proposed method.

## Usage

```
wp.mc.sem.boot(model, indirect = NULL, nobs = 100, nrep = 1000,
    nboot = 1000, alpha = 0.95, skewness = NULL, kurtosis = NULL,
    ovnames = NULL, se = "default", estimator = "default",
    parallel = "no", ncore = Sys.getenv("NUMBER_OF_PROCESSORS"), cl = NULL,
    ...)
```

## Arguments

model Model specified using lavaan syntax. More about model specification can be found in Rosseel (2012).
indirect Indirect effect difined using lavaan syntax.
nobs Sample size. It is 100 by default.
nrep $\quad$ Number of replications for the Monte Carlo simulation. It is 1000 by default.
nboot Number of replications for the bootstrap to test the specified parameter (e.g., mediation). It is 1000 by default.
alpha significance level chosed for the test. It equals 0.05 by default.
skewness A sequence of skewnesses of the observed variables. It is not required.
kurtosis A sequence of kurtosises of the observed variables. It is not required.
ovnames Names of the observed variables in the model. It is not required.

The method for calculatating the standard errors. Its default method "default" is regular standard errors. More about methods specification standard errors calculatationcan be found in Rosseel (2012).
estimator Estimator. It is Maxmum likelihood estimator by default. More about estimator specification can be found in Rosseel (2012).
parallel Parallel computing ("no" or "parallel" or "snow"). It is "no" by default, which means it will not use parallel computing. The option "parallel" is to use multiple cores in a computer for parallel computing. It is used with the number of cores (ncore). The option "snow" is to use clusters for parallel computing. It is used with the number of clusters (cl).
ncore Number of processors used for parallel computing. By default, ncore = Sys.getenv('NUMBER_OF_PROC
cl Number of clusters. It is NULL by default. When it is NULL, the program will detect the number of clusters automatically.
$\ldots \quad$ Extra arguments. It is not required.

## Value

An object of the power analysis. The power for all parameters in the model as well as the indirect effects if specified.

## wp.mc.sem. power.curve Statistical Power Curve for Structural Equation Modeling / Mediation based on Monte Carlo Simulation

## Description

A power curve is useful to graphically display how power changes with sample size (e.g., Zhang \& Wang). This function is to generate a power curve for SEM based on Monte Carlo simulation, either using Sobel test or bootstrap method to test the indirect / mediation effects if applicable.

## Usage

```
wp.mc.sem.power.curve(model, indirect = NULL, nobs = 100, type = "basic",
    nrep = 1000, nboot = 1000, alpha = 0.95, skewness = NULL,
    kurtosis = NULL, ovnames = NULL, se = "default",
    estimator = "default", parallel = "no",
    ncore = Sys.getenv("NUMBER_OF_PROCESSORS"), cl = NULL, ...)
```

## Arguments

model
Model specified using lavaan syntax. More about model specification can be found in Rosseel (2012).

| indirect | Indirect effect difined using lavaan syntax. <br> nobs |
| :--- | :--- |
| type | Sample size. It is 100 by default. <br> The method used to test the indirect effects (' basic' or 'boot '). By default <br> type='basic'. The type 'basic' is to use Sobel test (see also wp.mc.sem.basic), <br> while 'boot' is to use bootstrap method (see also wp.mc.sem.boot). |
| nrep | Number of replications for the Monte Carlo simulation. It is 1000 by default. <br> Number of replications for the bootstrap to test the specified parameter (e.g., <br> mediation). It is 1000 by default. |

skewness=c(1, 2), kurtosis=c(4, 6), type = c("two.sample"), alternative = c("less"))
```

wp.mediation Statistical Power Analysis for Simple Mediation

## Description

This function is for mediation models. Mediation models can be used to investigate the underlying mechanisms related to why an input variable x influences an output variable y (e.g., Hayes, 2013; MacKinnon, 2008). The mediation effect is calculated as $a^{*} b$, where $a$ is the path coefficent from the predictor x to the mediator m , and $b$ is the path coefficent from the mediator m to the outcome variable y. Sobel test statistic (Sobel, 1982) is used to test whether the mediation effect is significantly different from zero.

## Usage

wp.mediation( $\mathrm{n}=$ NULL, power $=$ NULL, $\mathrm{a}=0.5, \mathrm{~b}=0.5$, varx $=1$, vary $=1$, varm $=1$, alpha $=0.05$, interval $=$ NULL)

## Arguments

| n | Sample size. |
| :--- | :--- |
| power | Statistical power. |
| a | Coefficient from x to m. The default value is 0.5. |
| b | Coefficient from m to y. The default value is 0.5. |
| varx | Variance of x. The default value is 1. |
| vary | Variance of y. The default value is 1. |
| varm | Variance of m. The default value is 1. |
| alpha | significance level chosen for the test. It equals 0.05 by default. |
| interval | A vector containing the end-points of the interval to be searched for the root. |

## Value

An object of the power analysis.

wp.mmrm Power analysis for longitudinal data analysis

## Description

The two functions are adapted from the R package longpower by Michael C. Donohue. More will be added later.

## Usage

wp.mmrm( $\mathrm{N}=\mathrm{NULL}, \mathrm{Ra}=\mathrm{NULL}, \mathrm{ra}=\mathrm{NULL}$, sigmaa $=$ NULL,
Rb $=$ NULL, $r b=$ NULL, sigmab $=$ NULL, lambda $=1$,
delta $=$ NULL, alpha $=0.05$, power $=$ NULL,
alternative = c("two.sided", "one.sided"))
wp.mmrm.ar1 $(\mathrm{N}=$ NULL, $r$ ho $=$ NULL, $r a=$ NULL, sigmaa $=$ NULL,

```
rb = NULL, sigmab = NULL, lambda = 1, times = 1:length(ra),
delta = NULL, alpha = 0.05, power = NULL,
alternative = c("two.sided", "one.sided"))
```

## Arguments

| N | N |
| :--- | :--- |
| Ra | Ra |
| ra | ra |
| sigmaa | sigmaa |
| Rb | Rb |
| rb | rb |
| sigmab | sigmab |
| lambda | lambda |
| delta | delta |
| alpha | Significance level |
| power | Statistical power |
| alternative | alternative hypothesis |
| rho | rho |
| times | times |

## Description

power analysis of model 14 in Introduction to Mediation, Moderation, and Conditional Process Analysis

## Usage

wp.modmed.m14(
a1,
cp,
b1,
d1,
b2,
sige12,

```
    sige22,
    n,
    sigx_w,
    sigx2 = 1,
    sigw2 = 1,
    nrep = 1000,
    alpha = 0.05,
    b = 1000,
    nb = n,
    MCrep = 1000,
    w_value = 0,
    power_method = "product",
    simulation_method = "percentile",
    ncore = 1,
    pop.cov = NULL,
    mu = NULL,
    varnames = c("y", "x", "w", "m", "mw")
)
```

## Arguments

a1
$\mathrm{cp} \quad$ regression coefficient of outcome (y) on predictor ( x )
b1 regression coefficient of outcome (y) on mediator (m)
d1 regression coefficient of outcome (y) on moderator (w)
b2 regression coefficient of outcome (y) on the product (mw)
sige12 variance of error in the first regression equation
sige22 variance of error in the second regression equation
n sample size
sigx_w covariance between predictor (x) and moderator (w)
sigx2 variance of predictor (x)
sigw2 variance of moderator (w)
nrep number of replications for finding power
alpha type 1 error rate
b number of bootstrap iterations used when simulation method is "percentile"
$\mathrm{nb} \quad$ bootstrap sample size, default to n , used when simulation method is "percentile"
MCrep number of repetitions used for finding distribution when simulation method is "MC"
w_value moderator level
power_method "product" for using the indirect effect value in power calculation, or "joint" for using joint significance in power calculation
simulation_method
"percentile" for using percentile bootstrap CI in finding significance of mediation, or "MC" for using Monte Carlo CI in finding significance of mediation
ncore number of cores to use, default is 1 , when ncore $>1$, parallel is used
pop.cov covariance matrix, default to NULL if using the regression coefficient approach
mu mean vector, default to NULL if using the regression coefficient approach
varnames name of variables for the covariance matrix

## Value

power of indirect effect, direct effect, and moderation

## References

Statistical Power Analysis for Multisite Randomized Trials with 2 Arms

## Description

Multisite randomized trials (MRT) are a type of multilevel design for the situation when the entire cluster is randomly assigned to either a treatment arm or a control arm (Liu, 2013). The data from MRT can be analyzed in a two-level hierarchical linear model, where the indicator variable for treatment assignment is included in first level. If a study contains multiple treatments, then multiple indicators will be used. This function is for designs with 2 arms (i.e., a treatment and a control). Three types of tests are considered in the function: (1) The "main" type tests treatment main effect; (2) The "site" type tests the variance of cluster/site means; and (3) The "variance" type tests variance of treatment effects. Details leading to power calculation can be found in Raudenbush (1997) and Liu (2013).

## Usage

wp.mrt2arm(n = NULL, $f=$ NULL, $J=$ NULL, tau00 = NULL, tau11 = NULL, sg2 = NULL, power $=$ NULL, alpha = 0.05, alternative $=c(" t w o . s i d e d "$, "one.sided"), type = c("main", "site", "variance"), interval = NULL)

## Arguments

n
f

J

Sample size. It is the number of individuals within each cluster.
Effect size. It specifies the main effect of treatment, the mean difference between the treatment clusters/sites and the control clusters/sites. Effect size must be positive.
Number of clusters / sites. It tells how many clusters are considered in the study design. At least two clusters are required.

| tau00 | Variance of cluster/site means. It is one of the residual variances in the second <br> level. Its value must be positive. <br> Variance of treatment effects across sites. It is one of the residual variances in <br> the second level. Its value must be positive. |
| :--- | :--- |
| tau11 | Level-one error Variance. The residual variance in the first level. |
| sg2 | Statistical power. |
| power |  |
| alpha | significance level chosed for the test. It equals 0.05 by default. |
| alternative | Type of the alternative hypothesis ("two. sided" or "one.sided"). The default <br> is "two.sided". The option "one.sided" can be either "less" or "greater". |
| type | Type of effect ("main" or "site" or "variance") with "main" as default. The <br> type "main" tests treatment main effect, no tau00 needed; Type "site" tests the <br> variance of cluster/site means, no tau11 or f needed; and Type "variance" tests <br> variance of treatment effects, no tau00 or f needed. |
| interval | A vector containing the end-points of the interval to be searched for the root. |

## Value

An object of the power analysis.

## Description

Multisite randomized trials (MRT) are a type of multilevel design for the situation when the entire cluster is randomly assigned to either a treatment arm or a control arm (Liu, 2013). The data from MRT can be analyzed in a two-level hierarchical linear model, where the indicator variable for treatment assignment is included in first level. If a study contains multiple treatments, then multiple indicators will be used. This function is for designs with 3 arms (i.e., two treatments and a control). Three types of tests are considered in the function: (1) The "main" type tests treatment main effect; (2) The "treatment" type tests the difference between the two treatments; and (3) The "omnibus" type tests whether the three arms are all equivalent. Details leading to power calculation can be found in Raudenbush (1997) and Liu (2013).

## Usage

```
wp.mrt3arm(n = NULL, f1 = NULL, f2 = NULL, J = NULL, tau = NULL,
    sg2 = NULL, power = NULL, alpha = 0.05, alternative = c("two.sided",
    "one.sided"), type = c("main", "treatment", "omnibus"), interval = NULL)
```

## Arguments

$\mathrm{n} \quad$ Sample size. It is the number of individuals within each cluster.
f1 Effect size for treatment main effect. Effect size must be positive.
f2 Effect size for the difference between two treatments. Effect size must be positive.

J Number of clusters / sites. It tells how many clusters are considered in the study design. At least two clusters are required.
tau Variance of treatment effects across sites/clusters.
sg2 Level-one error Variance. The residual variance in the first level.
power Statistical power.
alpha significance level chosed for the test. It equals 0.05 by default.
alternative Type of the alternative hypothesis ("two.sided" or "one.sided"). The default is "two.sided". The option "one.sided" can be either "less" or "greater".
type Type of effect ("main" or "treatment" or "omnibus") with "main" as default. The type "main" tests the difference between the average treatment arms and the control arm; Type "treatment" tests the difference between the two treatment arms; and Type "omnibus" tests whether the three arms are all equivalent.
interval A vector containing the end-points of the interval to be searched for the root.

## Value

An object of the power analysis.

wp.poisson Statistical Power Analysis for Poisson Regression

## Description

This function is for Poisson regression models. Poisson regression is a type of generalized linear models where the outcomes are usually count data. Here, Maximum likelihood methods is used to estimate the model parameters. The estimated regression coefficent is assumed to follow a normal distribution. A Wald test is used to test the mean difference between the estimated parameter and the null parameter (tipically the null hypothesis assumes it equals 0 ). The procedure introduced by Demidenko (2007) is adopted here for computing the statistical power.

## Usage

```
wp.poisson(n = NULL, exp0 = NULL, exp1 = NULL, alpha = 0.05,
    power = NULL, alternative = c("two.sided", "less", "greater"),
    family = c("Bernoulli", "exponential", "lognormal", "normal", "Poisson",
    "uniform"), parameter = NULL, subdivisions=200L,
    i.method=c("numerical", "MC"), mc.iter=20000)
```

## Arguments

n
Sample size.

| exp0 | The base rate under the null hypothesis. It always takes positive value. See the <br> article by Demidenko (2007) for details. |
| :--- | :--- |
| exp1 | The relative increase of the event rate. It is used for calculatation of the effect <br> size. See the article by Demidenko (2007) for details. |
| alpha |  |
| power | significance level chosed for the test. It equals 0.05 by default. <br> alternative |
| Statistical power. |  |
| Direction of the alternative hypothesis ("two. sided" or "less" or "greater"). |  |
| The default is "two.sided". |  |

## Value

An object of the power analysis.

```

wp. popPar Extract Population Value Table

## Description

This function is used to extract population value table for parameters form an power analysis object for SEM based on Monte Carlo methods (class = 'power').

## Usage

wp. popPar(object)

## Arguments

object Object of power analysis. It is an object returned by a webpower function for SEM based on Monte Carlo methods with class = 'power'.

## Value

Population value table of parameters from the input object of power analysis.

## Description

Tests of proportions are a technique used to compare proportions of success or agreement in one or two samples. The one-sample test of proportion tests the null proportion of success, usually 0.5 . The two-sample test of proportions tests the null hypothesis that the two samples are drawn from populations with the same proportion of success. A z-test is used to evaluate whether the given difference in proportions is statistical significantly different from the null hypothesis. The power calculation is based on the arcsine transformation of the proportion (see Cohen, 1988, p.548).

## Usage

wp. prop(h = NULL, n1 = NULL, n2 = NULL, alpha = 0.05, power = NULL, type = c("1p", "2p", "2p2n"), alternative = c("two.sided", "less", "greater"))

## Arguments

h Effect size of the proportion comparison. Cohen (1992) suggested that effect size values of $0.2,0.5$, and 0.8 represent "small", "medium", and "large" effect sizes, repectively.
n1 Sample size of the first group.
n2 Sample size of the second group if applicable.
alpha Significance level chosed for the test. It equals 0.05 by default.
power Statistical power.
type Type of comparison (" 1 p " or " 2 p " or " 2 p 2 n "). The default is " 1 p ". 1 p : one sample; 2 p : two sample with equal sample size; 2 p 2 n : two sample with unequal sample size.
alternative Direction of the alternative hypothesis ("two.sided" or "less" or "greater"). The default is "two.sided".

## Value

An object of the power analysis.

## References

wp.regression Statistical Power Analysis for Linear Regression

## Description

This function is for power analysis for regression models. Regression is a statistical technique for examining the relationship between one or more independent variables (or predictors) and one dependent variable (or the outcome). Regression provides an F-statistic that can be formulated using the ratio between variation in the outcome variable that is explained by the predictors and the unexplained variation (Cohen, 1988)). The test statistc can also be experessed in terms of caomparison between Full and Reduced models (Maxwell \& Delaney, 2003).

## Usage

wp.regression( $\mathrm{n}=\mathrm{NULL}, \mathrm{p} 1=$ NULL, $\mathrm{p} 2=0, \mathrm{f} 2=$ NULL, alpha $=0.05$, power = NULL, type=c("regular", "Cohen"))

## Arguments

n
p1 Number of predictors in the full model.
p2 Number of predictors in the reduced moedel, it is 0 by default. See the book by Maxwell and Delaney (2003) for the definition of the reduced model.
f2 Effect size. We use the statistic f2 as the measure of effect size for linear regression proposed by Cohen(1988, p.410). Cohen discussed the effect size in three different cases. The calculation of f 2 can be generalized using the idea of a full model and a reduced model by Maxwell and Delaney (2003).
alpha significance level chosen for the test. It equals 0.05 by default.
power Statistical power.
type If set to "Cohen", the formula used in the Cohen's book will be used (not recommended).

## Value

An object of the power analysis

## Description

Repeated-measures ANOVA can be used to compare the means of a sequence of measurements (e.g., O’brien \& Kaiser, 1985). In a repeated-measures design, evey subject is exposed to all different treatments, or more commonly measured across different time points. Power analysis for (1) the within-effect test about the mean difference among measurements by default. If the subjects are from more than one group,the power analysis is also available for (2) the between-effect test about mean difference among groups and (3) the interaction effect test of the measurements and groups.

## Usage

wp.rmanova(n = NULL, ng = NULL, nm = NULL, f = NULL, nscor = 1, alpha $=0.05$, power $=$ NULL, type $=0$ )

## Arguments

| n |  |
| :--- | :--- |
| ng | Sample size. |
| nm | Number of groups. |
| f | Number of measurements. <br> Effect size. We use the statistic f as the measure of effect size for repeated- <br> measures ANOVA as in Cohen(1988, p.275). <br> Nonsphericity correction coefficient. The nonsphericity correction coefficient <br> is a measure of the degree of sphericity in the population. A coefficient of 1 <br> means sphericity is met, while a coefficient less than 1 means not met. The |
| samller value of the coefficient means the further departure from sphericity. The |  |
| lowest value of the coefficient is $1 /(\mathrm{nm}-1)$ where nm is the total number of mea- |  |
| surements. Two viable approaches for computing the empirical nonsphericity |  |
| correction coefficient are sggested. One is by Greenhouse and Geisser (1959), |  |
| the other is by Huynh and Feldt (1976). |  |

## Value

An object of the power analysis

wp.sem. chisq | Statistical Power Analysis for Structural Equation Modeling based on |
| :--- |
| Chi-Squared Test |

## Description

Structural equation modeling (SEM) is a multivariate technique used to analyze relationships among observed and latent variables. It can be viewed as a combination of factor analysis and multivariate regression analysis. Two methods are widely used in power analysis for SEM. One is based on the likelihood ratio test proposed by Satorra and Saris (1985). The other is based on RMSEA proposed by MacCallum et al. (1996). This function is for SEM power analysis based on the likelihood ratio test.

## Usage

wp.sem.chisq( $n=$ NULL, $d f=$ NULL, effect $=$ NULL, power $=$ NULL, alpha $=0.05$ )

## Arguments

n
Sample size.
df Degrees of freedom. The degrees of freedom of the chi-squared test.
effect Effect size. It specifies the population misfit of a SEM model, which is the difference between two SEM models: a full model (Mf) and a reduced model (Mr). A convienient way to get the effect size is to fit the reduced model using SEM software such R package 'lavaan' (Rossel, 2012). Then the effect size is calculated as the chi-squared statistics dividing by the sample size.
power Statistical power.
alpha significance level chosed for the test. It equals 0.05 by default.

## Value

An object of the power analysis.

## References

Statistical Power Analysis for Structural Equation Modeling based on RMSEA

## Description

Structural equation modeling (SEM) is a multivariate technique used to analyze relationships among observed and latent variables. It can be viewed as a combination of factor analysis and multivariate regression analysis. Two methods are widely used in power analysis for SEM. One is based on the likelihood ratio test proposed by Satorra and Saris (1985). The other is based on RMSEA proposed by MacCallum et al. (1996). This function is for SEM power analysis based on RMSEA.

## Usage

wp.sem.rmsea(n = NULL, df = NULL, rmsea0 = NULL, rmsea1 = NULL, power $=$ NULL, alpha $=0.05$, type $=c(" c l o s e ", ~ " n o t c l o s e "))$

## Arguments

n
df
rmsea0 RMSEA for H0. It usually euquals zero.
rmsea1 RMSEA for H1.
power Statistical power.
alpha significance level chosed for the test. It equals 0.05 by default.
type Close fit or non-clase fit ('close' or 'notclose'). It is 'close' by default.

## Value

An object of the power analysis.

## References

URL: http://psychstat.org/rmsea

## Description

A t-test is a statistical hypothesis test in which the test statistic follows a Student's t distribution if the null hypothesis is true and follows a non-central $t$ distribution if the alternative hypothesis is true. The $t$ test can assess the statistical significance of (1) the difference between population mean and a specific value, (2) the difference between two independent populaion means, and (3) difference between means of matched paires.

## Usage

```
wp.t(n1 = NULL, n2 = NULL, d = NULL, alpha = 0.05, power = NULL,
    type = c("two.sample", "one.sample", "paired", "two.sample.2n"),
    alternative = c("two.sided", "less", "greater"),
    tol = .Machine$double.eps^0.25)
```

## Arguments

| n 1 | Sample size of the first group. |
| :--- | :--- |
| n 2 | Sample size of the second group if applicable. |
| d | Effect size. See the book by Cohen (1988) for details. |
| alpha | Significance level chosed for the test. It equals 0.05 by default. <br> power <br> type |
|  | Statistical power. <br> Type of comparison ("one. sample" or "two. sample" or "two. sample. $2 \mathrm{n} "$ or <br> "two.sample. $2 \mathrm{n} "$ or "paired"). "two.sample" is two-sample t-test with equal |
| alternative | sample sizes, two.sample.2n" is two-sample t-test with unequal sample sizes, <br> "paired" is paired t-test <br> Direction of the alternative hypothesis ("two.sided" or "less" or "greater"). <br> The default is "two.sided". |
| tol | tolerance in root solver. |

## Value

An object of the power analysis.
